

Solving problems by searching

Chapter 3

Outline

- Problem-solving agents
- Problem types
- Problem formulation
- Example problems
- Basic search algorithms

Problem-solving agents

```
function SIMPLE-PROBLEM-SOLVING-AGENT(percept) returns an action
  static: seq, an action sequence, initially empty
           state, some description of the current world state
           goal, a goal, initially null
           problem, a problem formulation

  state  $\leftarrow$  UPDATE-STATE(state, percept)
  if seq is empty then do
    goal  $\leftarrow$  FORMULATE-GOAL(state)
    problem  $\leftarrow$  FORMULATE-PROBLEM(state, goal)
    seq  $\leftarrow$  SEARCH(problem)
  action  $\leftarrow$  FIRST(seq)
  seq  $\leftarrow$  REST(seq)
  return action
```

Example: Romania

- On holiday in Romania; currently in Arad.
- Flight leaves tomorrow from Bucharest
- **Formulate goal:**
 - be in Bucharest
- **Formulate problem:**
 - **states:** various cities
 - **actions:** drive between cities
- **Find solution:**
 - sequence of cities, e.g., Arad, Sibiu, Fagaras, Bucharest

Example: Romania

Single-state problem formulation

A **problem** is defined by four items:

1. **initial state** e.g., "at Arad"
 2. **actions** or **successor function** $S(x)$ = set of action–state pairs
 - e.g., $S(\text{Arad}) = \{ \langle \text{Arad} \rightarrow \text{Zerind}, \text{Zerind} \rangle, \dots \}$
 3. **goal test**, can be
 - **explicit**, e.g., $x = \text{"at Bucharest"}$
 - **implicit**, e.g., $\text{Checkmate}(x)$
 4. **path cost** (additive)
 - e.g., sum of distances, number of actions executed, etc.
 - $c(x, a, y)$ is the **step cost**, assumed to be ≥ 0
- A **solution** is a sequence of actions leading from the initial state to a goal state

Selecting a state space

- Real world is absurdly complex
 - state space must be **abstracted** for problem solving
- (Abstract) state = set of real states
- (Abstract) action = complex combination of real actions
 - e.g., "Arad □ Zerind" represents a complex set of possible routes, detours, rest stops, etc.
- For guaranteed realizability, **any** real state "in Arad" must get to **some** real state "in Zerind"
- (Abstract) solution =
 - set of real paths that are solutions in the real world
- Each abstract action should be "easier" than the original problem

Vacuum world state space graph

- states?
- actions?
- goal test?
- path cost?

Vacuum world state space graph

- states? integer dirt and robot location
- actions? *Left, Right, Suck*
- goal test? no dirt at all locations
- path cost? 1 per action

Example: The 8-puzzle

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

- states?
- actions?
- goal test?
- path cost?

Example: The 8-puzzle

7	2	4
5		6
8	3	1

Start State

	1	2
3	4	5
6	7	8

Goal State

- states? locations of tiles
- actions? move blank left, right, up, down
- goal test? = goal state (given)
- path cost? 1 per move

[Note: optimal solution of n -Puzzle family is hard]

Example: robotic assembly

- states?: real-valued coordinates of robot joint angles parts of the object to be assembled
- actions?: continuous motions of robot joints
- goal test?: complete assembly
- path cost?: time to execute

Tree search algorithms

- Basic idea:
 - offline, simulated exploration of state space by generating successors of already-explored states (a.k.a. ~expanding states)

```
function TREE-SEARCH(problem, strategy) returns a solution, or failure
  initialize the search tree using the initial state of problem
  loop do
    if there are no candidates for expansion then return failure
    choose a leaf node for expansion according to strategy
    if the node contains a goal state then return the corresponding solution
    else expand the node and add the resulting nodes to the search tree
```

Tree search example

Tree search example

Tree search example

Implementation: general tree search

```
function TREE-SEARCH(problem, fringe) returns a solution, or failure
  fringe  $\leftarrow$  INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe)
  loop do
    if fringe is empty then return failure
    node  $\leftarrow$  REMOVE-FRONT(fringe)
    if GOAL-TEST[problem](STATE[node]) then return SOLUTION(node)
    fringe  $\leftarrow$  INSERTALL(EXPAND(node, problem), fringe)
```

```
function EXPAND(node, problem) returns a set of nodes
  successors  $\leftarrow$  the empty set
  for each action, result in SUCCESSOR-FN[problem](STATE[node]) do
    s  $\leftarrow$  a new NODE
    PARENT-NODE[s]  $\leftarrow$  node; ACTION[s]  $\leftarrow$  action; STATE[s]  $\leftarrow$  result
    PATH-COST[s]  $\leftarrow$  PATH-COST[node] + STEP-COST(node, action, s)
    DEPTH[s]  $\leftarrow$  DEPTH[node] + 1
    add s to successors
  return successors
```

Implementation: states vs. nodes

- A **state** is a (representation of) a physical configuration
- A **node** is a data structure constituting part of a search tree includes **state**, **parent node**, **action**, **path cost** $g(x)$, **depth**

- The `Expand` function creates new nodes, filling in the various fields and using the `SuccessorFn` of the problem to create the corresponding states.

Search strategies

- A search strategy is defined by picking the **order of node expansion**
- Strategies are evaluated along the following dimensions:
 - **completeness**: does it always find a solution if one exists?
 - **time complexity**: number of nodes generated
 - **space complexity**: maximum number of nodes in memory
 - **optimality**: does it always find a least-cost solution?
- Time and space complexity are measured in terms of
 - b : maximum branching factor of the search tree
 - d : depth of the least-cost solution
 - m : maximum depth of the state space (may be ∞)

Uninformed search strategies

- **Uninformed** search strategies use only the information available in the problem definition
- Breadth-first search
- Uniform-cost search
- Depth-first search
- Depth-limited search
- Iterative deepening search

Breadth-first search

- Expand shallowest unexpanded node
- Implementation:
 - *fringe* is a FIFO queue, i.e., new successors go at end

Breadth-first search

- Expand shallowest unexpanded node
- Implementation:
 - *fringe* is a FIFO queue, i.e., new successors go at end

Breadth-first search

- Expand shallowest unexpanded node
- Implementation:
 - *fringe* is a FIFO queue, i.e., new successors go at end

Breadth-first search

- Expand shallowest unexpanded node
- **Implementation:**
 - *fringe* is a FIFO queue, i.e., new successors go at end

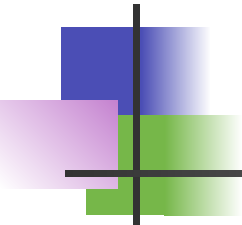

Properties of breadth-first search

- Complete? Yes (if b is finite)
- Time? $1+b+b^2+b^3+\dots +b^d + (b^{d+1}-b) = O(b^{d+1})$
- Space? $O(b^{d+1})$ (keeps every node in memory)
- Optimal? Yes (if cost = 1 per step)

- **Space** is the bigger problem (more than time)

Depth	Nodes	Time	Memory
2	1100	0,11 secs	1 Mb
4	111,100	11 secs	106 Mb
6	10^7	19 mins	10 gigabytes
8	10^9	31 hours	1 terabyte
10	10^{11}	129 days	101 terabyte
12	10^{13}	35 years	10 petabytes
14	10^{15}	3523 years	1 Exabyte

Time and Memory requirements to Breadth First Algorithm

Uniform-cost search

- Expand least-cost unexpanded node
- **Implementation:**
 - *fringe* = queue ordered by path cost
- Equivalent to breadth-first if step costs all equal
- Complete? Yes, if step cost $\geq \epsilon$
- Time? $O(b^{(C^*/\epsilon)})$ where C^* is the cost of the optimal solution
- Space? $O(b^{(C^*/\epsilon)})$
- Optimal? Yes – nodes expanded in increasing order of $g(n)$
 $b^{(C^*/\epsilon)} > b^d$
When all step costs are equal $b^{(C^*/\epsilon)} = b^d$

Depth-first search

- Expand deepest unexpanded node
- Implementation:
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

- Implementation:

Depth-first search

- Expand deepest unexpanded node
- **Implementation:**
 - *fringe* = LIFO queue, i.e., put successors at front

Properties of depth-first search

- Complete? No: fails in infinite-depth spaces, spaces with loops
 - Modify to avoid repeated states along path
 - complete in finite spaces
- Time? $O(b^m)$: terrible if m is much larger than d
 - but if solutions are dense, may be much faster than breadth-first
- Space? $O(bm)$, i.e., linear space!
- Optimal? No

Depth-limited search

= depth-first search with depth limit l ,
i.e., nodes at depth l have no successors

Recursive implementation:

```
function DEPTH-LIMITED-SEARCH(problem, limit) returns soln/fail/cutoff
  RECURSIVE-DLS(MAKE-NODE(INITIAL-STATE[problem]), problem, limit)

function RECURSIVE-DLS(node, problem, limit) returns soln/fail/cutoff
  cutoff-occurred?  $\leftarrow$  false
  if GOAL-TEST[problem](STATE[node]) then return SOLUTION(node)
  else if DEPTH[node] = limit then return cutoff
  else for each successor in EXPAND(node, problem) do
    result  $\leftarrow$  RECURSIVE-DLS(successor, problem, limit)
    if result = cutoff then cutoff-occurred?  $\leftarrow$  true
    else if result  $\neq$  failure then return result
  if cutoff-occurred? then return cutoff else return failure
```

Iterative deepening search

```
function ITERATIVE-DEEPENING-SEARCH( problem) returns a solution, or fail-  
ure  
  inputs: problem, a problem  
  for depth  $\leftarrow$  0 to  $\infty$  do  
    result  $\leftarrow$  DEPTH-LIMITED-SEARCH( problem, depth)  
    if result  $\neq$  cutoff then return result
```

Iterative deepening search / =0

Limit = 0

Iterative deepening search / =1

Limit = 1

Iterative deepening search / =2

Limit = 2

Iterative deepening search / =3

Limit = 3

Iterative deepening search

- Number of nodes generated in a depth-limited search to depth d with branching factor b :

$$N_{DLS} = b^0 + b^1 + b^2 + \dots + b^{d-2} + b^{d-1} + b^d$$

$$N_{BFS} = b + b^2 + \dots + b^d + (b^{d+1} - b)$$

- Number of nodes generated in an iterative deepening search to depth d with branching factor b :

$$N_{IDS} = d b + (d-1)b^2 + \dots + 3b^{d-2} + 2b^{d-1} + 1b^d$$

- For $b = 10$, $d = 5$,

- $N_{DLS} = 1 + 10 + 100 + 1,000 + 10,000 + 100,000 = 111,111$

- $N_{IDS} = 6 + 50 + 400 + 3,000 + 20,000 + 100,000 = 123,456$

- $N_{BFS} = 1,111,100$

- Overhead = $(123,456 - 111,111)/111,111 = 11\%$

Properties of iterative deepening search

- Complete? Yes
- Time? $(d+1)b^0 + d b^1 + (d-1)b^2 + \dots + b^d = O(b^d)$
- Space? $O(bd)$
- Optimal? Yes, if step cost = 1

Summary of algorithms

Criterion	Breadth-First	Uniform-Cost	Depth-First	Depth-Limited	Iterative Deepening
Complete?	Yes	Yes	No	No	Yes
Time	$O(b^{d+1})$	$O(b^{\lceil C^*/\epsilon \rceil})$	$O(b^m)$	$O(b^l)$	$O(b^d)$
Space	$O(b^{d+1})$	$O(b^{\lceil C^*/\epsilon \rceil})$	$O(bm)$	$O(bl)$	$O(bd)$
Optimal?	Yes	Yes	No	No	Yes

Repeated states

- Failure to detect repeated states can turn a linear problem into an exponential one!

Graph search

```
function GRAPH-SEARCH(problem, fringe) returns a solution, or failure
  closed ← an empty set
  fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe)
  loop do
    if fringe is empty then return failure
    node ← REMOVE-FRONT(fringe)
    if GOAL-TEST[problem](STATE[node]) then return SOLUTION(node)
    if STATE[node] is not in closed then
      add STATE[node] to closed
      fringe ← INSERTALL(EXPAND(node, problem), fringe)
```

Summary

- Problem formulation usually requires abstracting away real-world details to define a state space that can feasibly be explored
- Variety of uninformed search strategies
- Iterative deepening search uses only linear space and not much more time than other uninformed algorithms

Problem types

- Deterministic, fully observable □ single-state problem
 - Agent knows exactly which state it will be in; solution is a sequence
- Non-observable □ sensorless problem (conformant problem)
 - Agent may have no idea where it is; solution is a sequence
- Nondeterministic and/or partially observable □ contingency problem
 - percepts provide new information about current state
 - often interleave} search, execution
- Unknown state space □ exploration problem

Example: vacuum world

- Single-state, start in #5.

Solution?

Example: vacuum world

- Single-state, start in #5.
Solution? [*Right, Suck*]

- Sensorless, start in
 $\{1,2,3,4,5,6,7,8\}$ e.g.,
Right goes to $\{2,4,6,8\}$
Solution?

Example: vacuum world

- Sensorless, start in $\{1,2,3,4,5,6,7,8\}$ e.g.,
Right goes to $\{2,4,6,8\}$

Solution?

[Right, Suck, Left, Suck]

- Contingency

- Nondeterministic: *Suck* may dirty a clean carpet
- Partially observable: location, dirt at current location.
- Percept: $[L, \text{Clean}]$, i.e., start in #5 or #7

Solution?

Example: vacuum world

- Sensorless, start in $\{1,2,3,4,5,6,7,8\}$ e.g.,
Right goes to $\{2,4,6,8\}$

Solution?

[Right, Suck, Left, Suck]

■ Contingency

- Nondeterministic: *Suck* may dirty a clean carpet
- Partially observable: location, dirt at current location.
- Percept: $[L, \text{Clean}]$, i.e., start in #5 or #7

Solution? *[Right, **if dirt then Suck**]*
